ON A PROBLEM OF ARNOLD: THE AVERAGE MULTIPLICATIVE ORDER OF A GIVEN INTEGER

PÅR KURLBERG AND CARL POMERANCE

Abstract. For \( g, n \) coprime integers, let \( \ell_g(n) \) denote the multiplicative order of \( g \) modulo \( n \). Motivated by a conjecture of Arnold, we study the average of \( \ell_g(n) \) as \( n \leq x \) ranges over integers coprime to \( g \), and \( x \) tending to infinity. Assuming the Generalized Riemann Hypothesis, we show that this average is essentially as large as the average of the Carmichael lambda function. We also determine the asymptotics of the average of \( \ell_g(p) \) as \( p \leq x \) ranges over primes.

1. Introduction

Given coprime integers \( g, n \) with \( n > 0 \) and \(|g| > 1\), let \( \ell_g(n) \) denote the multiplicative order of \( g \) modulo \( n \), i.e., the smallest integer \( k \geq 1 \) such that \( g^k \equiv 1 \mod n \). For \( x \geq 1 \) an integer let

\[
T_g(x) := \frac{1}{x} \sum_{n \leq x, (n, g) = 1} \ell_g(n),
\]

essentially the average multiplicative order of \( g \). In [1], Arnold conjectured that if \(|g| > 1\), then

\[
T_g(x) \sim c(g) \frac{x}{\log x},
\]
as \( x \to \infty \), for some constant \( c(g) > 0 \). However, in [11] Shparlinski showed that if the Generalized Riemann Hypothesis\(^1\) (GRH) is true, then

\[
T_g(x) \gg \frac{x}{\log x} \exp \left( C(g) (\log \log \log x)^{3/2} \right),
\]

\(^1\)What is needed is that the Riemann hypothesis holds for Dedekind zeta functions \( \zeta_{K_n}(s) \) for all \( n > 1 \), where \( K_n \) is the Kummer extension \( \mathbb{Q}(e^{2\pi i/n}, g^{1/n}) \).
where \(C(g) > 0\). He also suggested that it should be possible to obtain, again assuming GRH, a lower bound of the form

\[
T_g(x) \geq \frac{x}{\log x} \exp \left( \left( \log \log \log \log x \right) \right),
\]
as \(x \to \infty\).

Let

\[
B = e^{-\gamma} \prod_p \left( 1 - \frac{1}{(p-1)^2 (p+1)} \right) = 0.3453720641 \ldots,
\]

the product being over primes, and where \(\gamma\) is the Euler–Mascheroni constant. The principal aim of this paper is to prove the following result.

**Theorem 1.** Assuming the GRH,

\[
T_g(x) = \frac{x}{\log x} \exp \left( \frac{B \log \log x}{\log \log \log x} (1 + o(1)) \right)
\]
as \(x \to \infty\), uniformly in \(g\) with \(1 < |g| \leq \log x\). The upper bound implicit in this result holds unconditionally.

Let \(\lambda(n)\) denote the exponent of the group \((\mathbb{Z}/n\mathbb{Z})^\times\). Commonly known as Carmichael’s function, we have \(\ell_g(n) \leq \lambda(n)\) when \((g,n) = 1\), so we immediately obtain that

\[
T_g(x) \leq \frac{1}{x} \sum_{n \leq x} \lambda(n),
\]

and it is via this inequality that we are able to unconditionally establish the upper bound implicit in Theorem 1. Indeed, in [2], Erdös, Pomerance, and Schmutz determined the average order of \(\lambda(n)\) showing that, as \(x \to \infty\),

\[
\frac{1}{x} \sum_{n \leq x} \lambda(n) = \frac{x}{\log x} \exp \left( \frac{B \log \log x}{\log \log \log x} (1 + o(1)) \right).
\]

Theorem 1 thus shows under assumption of the GRH that the mean values of \(\lambda(n)\) and \(\ell_g(n)\) are of a similar order of magnitude. We know, on assuming the GRH, that \(\lambda(n)/\ell_g(n)\) is very small for almost all \(n\) (e.g., see [4, 7]; in the latter paper Li and Pomerance in fact showed that \(\lambda(n)/\ell_g(n) \leq (\log n)^{\omega(\log \log \log n)}\) as \(n \to \infty\) on a set of asymptotic density 1), so perhaps Theorem 1 is not very surprising. However, in [2] it was also shown that the normal order of \(\lambda(n)\) is quite a bit smaller
than the average order: there exists a subset $S$ of the positive integers, of asymptotic density 1, such that for $n \in S$ and $n \to \infty$,

$$\lambda(n) = \frac{n}{(\log n)^{\log \log n + A + (\log \log \log n)^{-1+o(1)}}},$$

where $A > 0$ is an explicit constant. Thus the main contribution to the average of $\lambda(n)$ comes from a density-zero subset of the integers, and to obtain our result on the average multiplicative order, we must show that $\ell_g(n)$ is large for many $n$ for which $\lambda(n)$ is large.

We remark that if one averages over $g$ as well, then a result like our Theorem 1 holds unconditionally. In particular, it follows from Luca and Shparlinski [9, Theorem 6] that

$$\frac{1}{x^2} \sum_{n \leq x} \sum_{1 < g < n \ (g,n)=1} \ell_g(n) = \frac{x}{\log x} \exp \left( \frac{B \log \log x}{\log \log \log x} (1 + o(1)) \right)$$

as $x \to \infty$.

We also note that our methods give that Theorem 1 still holds for $g = a/b$ a rational number, with uniform error for $|a|, |b| \leq \log x$, and $n$ ranging over integers coprime to $ab$.

1.1. Averaging over prime moduli. We shall always have the letters $p, q$ denoting prime numbers. Given a rational number $g \neq 0, \pm 1$ and a prime $p$ not dividing the numerator or denominator of $g$, let $\ell_g(p)$ denote the multiplicative order of $g$ modulo $p$. For simplicity, when $p$ does divide the numerator or denominator of $g$, we let $\ell_g(p) = 1$. Further, given $k \in \mathbb{Z}^+$, let

$$D_g(k) := [\mathbb{Q}(g^{1/k}, e^{2\pi i/k}) : \mathbb{Q}]$$

denote the degree of the Kummer extension obtained by taking the splitting field of $X^k - g$. Let $\text{rad}(k)$ denote the largest squarefree divisor of $k$ and let $\omega(k)$ be the number of primes dividing $\text{rad}(k)$.

**Theorem 2.** Given $g \in \mathbb{Q}$, $g \neq 0, \pm 1$, define

$$c_g := \sum_{k=1}^{\infty} \frac{\phi(k) \text{rad}(k)(-1)^{\omega(k)}}{k^2 D_g(k)}.$$

The series for $c_g$ converges absolutely, and, assuming the GRH,

$$\frac{1}{\pi(x)} \sum_{p \leq x} \ell_g(p) = \frac{1}{2} c_g \cdot x + O \left( \frac{x}{(\log x)^{1/2-2/\log \log \log x}} \right).$$

Further, with $g = a/b$ where $a, b \in \mathbb{Z}$, the error estimate holds uniformly for $|a|, |b| \leq x$. 

This result might be compared with Pappalardi [10]. In fact, his method suggests an alternate route to our Theorem 2, and would allow the upper bound

\[ \frac{1}{\pi(x)} \sum_{p \leq x} \ell_g(p) \leq \frac{1}{2}(c_g + o(1))x, \]

as \( x \to \infty \), to be established unconditionally. The advantage of our method is that it avoids computing the density of primes where \( g \) has a given index.

At the heart of our claims of uniformity, both in Theorems 1 and 2, is our Theorem 6 in Section 2. Though perhaps not obvious from the definition, \( c_g > 0 \) for all \( g \neq 0, \pm 1 \). In order to determine \( c_g \), define

\[ c := \prod_p \left( 1 - \frac{p}{p^3 - 1} \right) = 0.5759599689 \ldots, \]

the product being over primes; \( c_g \) turns out to be a positive rational multiple of \( c \). Theorem 2 should be contrasted with the unconditional result of Luca [8] that

\[ \frac{1}{\pi(x)} \sum_{p \leq x} \frac{1}{\ell_g(p)} = c + O(1/(\log x)^\kappa) \]

for any fixed \( \kappa > 0 \). By partial summation one can then obtain

\[ \frac{1}{\pi(x)} \sum_{p \leq x} \frac{1}{p - 1} \sum_{g=1}^{p-1} \ell_g(p) \sim \frac{1}{2} c \cdot x \text{ as } x \to \infty, \]

a result that is more comparable to Theorem 2.

To sum the series that defines \( c_g \) we will need some further notation. For \( p \) a prime and \( \alpha \in \mathbb{Q}^* \), let \( v_p(\alpha) \) be the exponential \( p \)-valuation at \( \alpha \), that is, it is the integer for which \( p^{-v_p(\alpha)} \alpha \) is invertible modulo \( p \). Write \( g = \pm g_0^h \) where \( h \) is a positive integer and \( g_0 > 0 \) is not an exact power of a rational number, and write \( g_0 = g_1 g_2^2 \) where \( g_1 \) is a squarefree integer and \( g_2 \) is a rational. Let \( e = v_2(h) \) and define \( \Delta(g) = g_1 \) if \( g_1 \equiv 1 \mod 4 \), and \( \Delta(g) = 4g_1 \) if \( g_1 \equiv 2 \) or \( 3 \mod 4 \). For \( g > 0 \), define \( n = \text{lcm}[2^{e+1}, \Delta(g)] \). For \( g < 0 \), define \( n = 2g_1 \) if \( e = 0 \) and \( g_1 \equiv 3 \mod 4 \), or \( e = 1 \) and \( g_1 \equiv 2 \mod 4 \); let \( n = \text{lcm}[2^{e+2}, \Delta(g)] \) otherwise.

Consider the multiplicative function \( f(k) = (-1)^{\omega(k)} \text{rad}(k)(h,k)/k^3 \). We note that for \( p \) prime and \( j \geq 1 \),

\[ f(p^j) = -p^{1-3j+\min(j,v_p(h))}. \]
Given an integer \( t \geq 1 \), define \( F(p, t) \) and \( F(p) \) by
\[
F(p, t) := \sum_{j=0}^{t-1} f(p^j), \quad F(p) := \sum_{j=0}^{\infty} f(p^j)
\]
In particular, we note that if \( p \nmid h \), then
\[
F(p) = 1 - \sum_{j=1}^{\infty} p^{1-3j} = 1 - \frac{p}{p^3 - 1}.
\]

**Proposition 3.** With notation as above, if \( g < 0 \) and \( e > 0 \), we have
\[
c_g = c \cdot \prod_{p|h} \frac{F(p)}{1 - \frac{p}{p^3 - 1}} \cdot \left( 1 - \frac{F(2, e + 1)}{2F(2)} \right) + \prod_{p|n} \left( 1 - \frac{F(p,v_p(n))}{F(p)} \right),
\]
otherwise
\[
c_g = c \cdot \prod_{p|h} \frac{F(p)}{1 - \frac{p}{p^3 - 1}} \cdot \left( 1 + \prod_{p|n} \left( 1 - \frac{F(p,v_p(n))}{F(p)} \right) \right).
\]

For example, if \( g = 2 \), then \( h = 1 \), \( e = 0 \), and \( n = 8 \). Thus
\[
c_2 = c \cdot \left( 1 + 1 - \frac{F(2, 3)}{F(2)} \right) = c \cdot \left( 2 - \frac{1 - 2/(2^1)^3 - 2/(2^2)^3}{1 - 2/(8 - 1)} \right) = c \cdot \frac{159}{160}.
\]

2. Some preliminary results

For an integer \( m \geq 2 \), we let \( P(m) \) denote the largest prime dividing \( m \), and we let \( P(1) = 1 \).

Given a rational number \( g \neq 0, \pm 1 \), we recall the notation \( h, e, n \) described in Section 1.1, and for a positive integer \( k \), we recall that \( D_g(k) \) is the degree of the splitting field of \( X^k - g \) over \( \mathbb{Q} \). We record a result of Wagstaff on \( D_g(k) \), see [12], Proposition 4.1 and the second paragraph in the proof of Theorem 2.2.

**Proposition 4.** With notation as above,
\[
D_g(k) = \frac{\phi(k) \cdot k}{(k,h) \cdot \epsilon_g(k)}
\]
where \( \phi \) is Euler’s function and \( \epsilon_g(k) \) is defined as follows: If \( g > 0 \), then
\[
\epsilon_g(k) := \begin{cases} 
2 & \text{if } n | k, \\
1 & \text{if } n \nmid k.
\end{cases}
\]
If $g < 0$, then
\[
\epsilon_g(k) := \begin{cases} 
2 & \text{if } n|k, \\
1/2 & \text{if } 2|k \text{ and } 2^{e+1} \nmid k, \\
1 & \text{otherwise.}
\end{cases}
\]

We also record a GRH-conditional version of the Chebotarev density theorem for Kummerian fields over $\mathbb{Q}$, see Hooley [3, Sec. 5] and Lagarias and Odlyzko [6, Theorem 1]. Let $i_g(p) = (p - 1)/\ell_g(p)$, the index of $\langle g \rangle$ in $\mathbb{Z}/p\mathbb{Z}^*$ when $g \in (\mathbb{Z}/p\mathbb{Z})^*$.

**Theorem 5.** Assume the GRH. Suppose $g = a/b \neq 0, \pm 1$ where $a, b$ are integers of absolute value at most $x$. For each integer $k \leq x$, we have that the number of primes $p \leq x$ for which $k \mid i_g(p)$ is
\[
\frac{1}{D_g(k)} \pi(x) + O(x^{1/2} \log x).
\]

Note that $k \mid i_g(p)$ if and only if $x^k - g$ splits completely modulo $p$. Also note that the trivial bound $x/k$ is majorized by the error term in Theorem 5 when $k \geq x^{1/2}/\log x$. In fact, the error term majorizes the main term for $k \geq x^{1/4}$.

We will need the following uniform version of [5, Theorem 23].

**Theorem 6.** If the GRH is true, then for $x, L$ with $1 \leq L \leq \log x$ and $g = a/b \neq 0, \pm 1$ where $a, b$ are integers with $|a|, |b| \leq x$, we have
\[
\left| \left\{ p \leq x : \ell_g(p) \leq \frac{p - 1}{L} \right\} \right| \ll \frac{\pi(x)}{L} \cdot \frac{\phi(h)}{\phi(h)} + \frac{x \log \log x}{\log^2 x}
\]
uniformly, where $\tau(h)$ is the number of divisors of $h$.

**Proof.** Since the proof is rather similar to the proof of the main theorem in [3], [4, Theorem 2], and [5, Theorem 23], we only give a brief outline. We see that $\ell_g(p) \leq (p - 1)/L$ implies that $i_g(p) \geq L$. Further, in the case that $p \mid ab$, where we are defining $\ell_g(p) = 1$ and hence $i_g(p) = p - 1$, the number of primes $p$ is $O(\log x)$. So we assume that $p \nmid ab$.

**First step:** Consider primes $p \leq x$ such that $i_g(p) > x^{1/2} \log^2 x$. Such a prime $p$ divides $a^k - b^k$ for some positive integer $k < x^{1/2}/\log^2 x$. Since $\omega(|a^k - b^k|) \ll k \log x$, it follows that the number of primes $p$ in this case is $O((x^{1/2}/\log^2 x)^2 \log x) = O(x/\log^3 x)$.

**Second step:** Consider primes $p$ such that $q \mid i_g(p)$ for some prime $q$ in the interval $I := \left[\frac{x^{1/2}}{\log x}, x^{1/2} \log^2 x\right]$. We may bound this by considering primes $p \leq x$ such that $p \equiv 1 \pmod{q}$ for some prime $q \in I$. The Brun–Titchmarsh inequality then gives that the number of such primes $p$ is
at most a constant times
\[ \sum_{q \in I} \frac{x}{\phi(q) \log(x/q)} \ll \frac{x}{\log x} \sum_{q \in I} \frac{1}{q} \ll \frac{x \log \log x}{\log^2 x}. \]

Third step: Now consider primes \( p \) such that \( q \mid i_g(p) \) for some prime \( q \) in the interval \([L, \frac{x^{1/2}}{\log^2 x}]\). In this range we use Proposition 4 and Theorem 5 to get on the GRH that
\[ |\{ p \mid p \leq x : q \mid i_g(p) \}| \ll \frac{\pi(x)(q, h)}{q\phi(q)} + x^{1/2} \log x. \]
Summing over primes \( q \), we find that the number of such \( p \) is bounded by a constant times
\[ \sum_{q \in [L, \frac{x^{1/2}}{\log^2 x}]} \left( \frac{\pi(x)(q, h)}{q^2} + x^{1/2} \log x \right) \ll \frac{\pi(x) \omega(h)}{L} + \frac{x}{\log^2 x}. \]

Fourth step: For the remaining primes \( p \), any prime divisor \( q \mid i_g(p) \) is smaller than \( L \). Hence \( i_g(p) \) must be divisible by some integer \( d \) in the interval \([L, L^2]\). By Proposition 4 and Theorem 5, assuming the GRH, we have
\[ |\{ p \mid p \leq x : d \mid i_g(p) \}| \leq 2 \frac{\pi(x)(d, h)}{d\phi(d)} + O(x^{1/2} \log x). \]
Hence the total number of such \( p \) is bounded by
\[ \sum_{d \in [L, L^2]} \left( 2 \frac{\pi(x)(d, h)}{d\phi(d)} + O(x^{1/2} \log x) \right) \ll \frac{\pi(x) h\tau(h)}{L \phi(h)}, \]
where the last estimate follows from
\[ \sum_{d \in [L, L^2]} \frac{(d, h)}{d\phi(d)} \leq \sum_{m|h} \sum_{d \in [L, L^2]} \frac{m}{d\phi(d)} \leq \sum_{m|h} \sum_{k \geq L/m} \frac{1}{\phi(m)k\phi(k)} \ll \sum_{m|h} \frac{m}{L\phi(m)} = \frac{h}{L\phi(h)} \sum_{m|h} \frac{m}{\phi(m)} \cdot \frac{\phi(h)}{h} \leq \frac{h\tau(h)}{L\phi(h)}. \]
Here we used the bound \( \sum_{k \geq T} \frac{1}{k\phi(k)} \ll 1/T \) for \( T > 0 \), which follows by an elementary argument from the bound \( \sum_{k \geq T} \frac{1}{k^2} \ll 1/T \) and the identity \( k/\phi(k) = \sum_{j|k} \frac{\mu^2(j)}{\phi(j)j^2} \). Indeed,
\[ \sum_{k \geq T} \frac{1}{k\phi(k)} = \sum_j \frac{\mu^2(j)}{\phi(j)j^2} \sum_{l \geq T/j} \frac{1}{l^2} \ll \frac{1}{T} \sum_{j \leq T} \frac{1}{\phi(j)j} + \sum_{j > T} \frac{1}{j^2} \ll \frac{1}{T}. \]
\( \square \)
Corollary 7. Assume the GRH is true. Let $m \geq 2$ be an integer and $x \geq 10^7$ a real number. Let $y = \log \log x$ and assume that $m \leq \log y/\log \log y$. Let $g = a/b \neq 0, \pm 1$ where $a, b$ are integers with $|a|, |b| \leq \exp((\log x)^{3/m})$, and let $h$ be as above. Then uniformly,

$$
\sum_{p \leq x} \frac{1}{p} \ll y \left( \frac{1}{m} + \sum_{q \mid h, \ q > m} \frac{1}{q} \right).
$$

Proof. This result is more a corollary of the proof of Theorem 6 than its statement. We consider intervals $I_j := (e^{j}, e^{j+1}]$ for $j \leq \log x$, $j$ a non-negative integer. The sum of reciprocals of all primes $p \leq \exp((\log x)^{1/m})$ is $y/m + O(1)$, so this contribution to the sum is under control. We thus may restrict to the consideration of primes $p \in I_j$ for $j > (\log x)^{1/m}$. For such an integer $j$, let $t = e^{j+1}$. If $q \mid i_q(p)$ for some prime $q > t^{1/2} \log^2 t$, then $\ell_q(p) \leq t^{1/2} / \log^2 t$, and the number of such primes is $O(\sum_{k \leq t^{1/2} / \log^2 t} k \log |ab|) = O(t \log |ab|/\log^4 t)$, so that the sum of their reciprocals is $O(\log |ab|/\log^4 t) = O((\log x)^{3/m}/j^4)$. Summing this for $j > (\log x)^{1/m}$, we get $O(1)$, which is acceptable.

For $J := (t^{1/2} / \log^2 t, t^{1/2} \log^2 t]$, with $t = e^{j+1}$, we have that the reciprocal sum of the primes $p \in I_j$ with some $q \in J$ dividing $i_q(p)$ (so that $q \mid p - 1$) is $O(\log \log t / \log^2 t) = O(\log j / j^2)$. Summing this for $j > (\log x)^{1/m}$ is $o(1)$ as $x \to \infty$ and is acceptable.

For $q \leq t^{1/2} / \log^2 t$ we need the GRH. As in the proof of Theorem 6, the number of primes $p \in I_j$ with $q \mid i_q(p)$ is bounded by a constant times

$$
\frac{t}{\log t} \frac{(q, h)}{q^2 j^2} + t^{1/2} \log t.
$$

Thus, the reciprocal sum of these primes $p$ is

$$
O \left( \frac{(q, h)}{q^2 \log t} + \frac{\log t}{t^{1/2}} \right) = O \left( \frac{(q, h)}{q^2 j^2} + \frac{j}{e^{j/2}} \right).
$$

We sum this expression over primes $q$ with $m < q \ll e^{j/2}/j^2$ getting

$$
O \left( \frac{1}{jm \log m} + \frac{1}{j} \sum_{q \mid h, \ q > m} \frac{1}{q} + \frac{1}{j^2} \right).
$$

Summing on $j \leq \log x$ completes the proof. \qed

3. PROOF OF THEOREM 1

Let $x$ be large and let $g$ be an integer with $1 < |g| \leq \log x$. Define $y = \log \log x$, $m = \lfloor y/\log^3 y \rfloor$, $D = m!$,
and let

\[ S_k = \{ p \leq x : (p - 1, D) = 2k \}. \]

Then \( S_1, S_2, \ldots, S_{D/2} \) are disjoint sets of primes whose union equals \( \{ 2 < p \leq x \} \). Let

\[
\tilde{S}_k = \left\{ p \in S_k : p \nmid g, \frac{p - 1}{2k} \mid \ell_g(p) \right\}
\]

be the subset of \( S_k \) where \( \ell_g(p) \) is “large.” Note that if \( k \leq \log y \), \( p \in S_k \setminus \tilde{S}_k \), and \( p \nmid g \), there is some prime \( q > m \) with \( q \mid (p - 1)/\ell_g(p) \), so that \( P(i_g(p)) > m \). Indeed, for \( x \) sufficiently large, we have \( \log y \leq m/2 \), and thus \( k \leq \log y \) implies that each prime dividing \( D \) also divides \( D/(2k) \), so that \( (p - 1, D) = 2k \) implies that the least prime factor of \( (p - 1)/(2k) \) exceeds \( m \).

Thus, from Theorem 6,

\[
|S_k \setminus \tilde{S}_k| \leq |\{ p \leq x : \ell_g(p) < p/m \}| + \sum_{p \mid g} \frac{\pi(x)}{m} \cdot \frac{h\tau(h)}{\phi(h)}
\]

uniformly for \( k \leq \log y \). Using this it is easy to see that \( S_k \) and \( \tilde{S}_k \) are of similar size when \( k \) is small. However, we shall essentially measure the “size” of \( S_k \) or \( \tilde{S}_k \) by the sum of the reciprocals of its members and for this we will use Corollary 7. We define

\[ E_k := \sum_{\substack{p \in S_k \cap [1, x] \ \text{and} \ 1 < p^\alpha \leq x}} \frac{1}{p^\alpha} \]

and

\[ \tilde{E}_k := \sum_{\substack{p \in \tilde{S}_k \cap [1, x] \ \text{and} \ 1 < p^\alpha \leq x}} \frac{1}{p^\alpha}. \]

By Lemma 1 of [2], uniformly for \( k \leq \log^2 y \),

\[ E_k = \frac{y}{\log y} \cdot P_k \cdot (1 + o(1)) \]

where

\[ P_k = \frac{e^{-\gamma}}{k} \prod_{q > 2} \left(1 - \frac{1}{(q - 1)^2}\right) \prod_{1 < k, q > 2} \frac{q - 1}{q - 2}. \]

Note that, with \( B \) given by (1),

\[ \sum_{k=1}^{\infty} \frac{P_k}{2k} = B. \]
The following lemma shows that not much is lost when restricting to primes \( p \in \tilde{S}_k \).

**Lemma 8.** For \( k \leq \log y \), we uniformly have
\[
\tilde{E}_k = E_k \cdot \left( 1 + O \left( \frac{\log^5 y}{y} \right) \right).
\]

**Proof.** By (8) and (9), we have
\[
E_k \gg \frac{y}{k \log y} \geq \frac{y}{\log^2 y},
\]
and it is thus sufficient to show that \( \sum_{p \in S_k \setminus \tilde{S}_k} \frac{1}{p} \ll \log^3 y \) since the contribution from prime powers \( p^\alpha \) for \( \alpha \geq 2 \) is \( O(1) \). As we have seen, if \( k \leq \log y \) and \( p \in S_k \setminus \tilde{S}_k \) then either \( p \mid g \) or \( P(t_g(p)) > m \). Hence, using Corollary 7 and noting that the hypothesis \( |g| \leq \log x \) implies that \( h \ll y \) and so \( h \) has at most one prime factor \( q > m \), we have
\[
\sum_{p \in E_k \setminus \tilde{E}_k} \frac{1}{p} \ll \frac{y}{m} = \frac{y}{\lfloor y/\log^3 y \rfloor} \ll \log^3 y.
\]
This completes the proof. \( \square \)

**Lemma 9.** We have
\[
\sum_{k \leq \log y} \frac{E_k}{2k} = \frac{B y}{\log y} (1 + o(1))
\]
where \( B \) is given by (1).

**Proof.** This follows immediately from (8), (9), and (10). \( \square \)

Given a vector \( \mathbf{j} = (j_1, j_2, \ldots, j_{D/2}) \) with each \( j_i \in \mathbb{Z}_{\geq 0} \), let
\[
\|\mathbf{j}\| := j_1 + j_2 + \ldots + j_{D/2}.
\]
Paralleling the notation \( \Omega_i(x; \mathbf{j}) \) from [2], let:
- \( \tilde{\Omega}_1(x; \mathbf{j}) \) be the set of integers that can be formed by taking products of \( v = \|\mathbf{j}\| \) distinct primes \( p_1, p_2, \ldots, p_v \) in such a way that:
  - for each \( i \), \( p_i < x^{1/y} \), and
  - the first \( j_1 \) primes are in \( \tilde{S}_1 \), the next \( j_2 \) are in \( \tilde{S}_2 \), etc.;
- \( \tilde{\Omega}_2(x; \mathbf{j}) \) be the set of integers \( u = p_1 p_2 \cdots p_v \in \tilde{\Omega}_1(x; \mathbf{j}) \) such that \( (p_i - 1, p_j - 1) \) divides \( D \) for all \( i \neq j \);
- \( \tilde{\Omega}_3(x; \mathbf{j}) \) be the set of integers of the form \( n = up \) where \( u \in \tilde{\Omega}_2(x; \mathbf{j}) \) and \( p \) satisfies \( (p - 1, D) = 2 \), \( \max(x/(2u), x^{1/y}) < p \leq x/u \) and \( \ell_g(p) > p/y^2 \).
\[
\tilde{\Omega}_4(x; j) \text{ be the set of integers } n = (p_1 p_2 \cdots p_v) p \text{ in } \tilde{\Omega}_3(x; j) \text{ with the additional property that } (p - 1, p_i - 1) = 2 \text{ for all } i.
\]
(In the third bullet, note that the max is not strictly necessary since when } x \text{ is sufficiently large, } x/(2u) > x^{1/y}. \]

3.1. Some lemmas. We shall also need the following analogues of Lemmas 2-4 of [2]. Let \[ J := \{ j : 0 \leq j_k \leq E_k/k \text{ for } k \leq \log y, \text{ and } j_k = 0 \text{ for } k > \log y \}. \]

Lemma 10. If } j \in J, \ n \in \tilde{\Omega}_4(x; j), \text{ and } x \geq x_1, \text{ then}
\[
\ell_g(n) \geq c_1 \frac{x}{y^3} \prod_{k \leq \log y} (2k)^{-j_k},
\]
where } x_1, c_1 > 0 \text{ are absolute constants.}

Proof. Suppose that } n = (p_1 p_2 \cdots p_v) p \in \tilde{\Omega}_4(x; j). \text{ Let } d_i := (p_i - 1, D), \text{ and let } u_i := (p_i - 1)/d_i. \text{ By (7), } u_i \text{ divides } \ell_g(p_i) \text{ for all } i, \text{ and by the definition of } \tilde{\Omega}_3(x; j) \text{ we also have } \ell_g(p) > p/y^2. \text{ Since } (p - 1)/2 \text{ is coprime to } (p_i - 1)/2 \text{ for each } i \text{ and each } (p_i - 1, p_j - 1) \mid D \text{ for } i \neq j, \text{ we have } u_1, \ldots, u_v, p - 1 \text{ pairwise coprime. But}
\[
\ell_g(n) = \text{lcm}[\ell_g(p_1), \ell_g(p_2), \ldots, \ell_g(p_v), \ell_g(p)],
\]
so we find that, using the minimal order of Euler’s function and } \ell_g(p) > p/y^2,
\[
\ell_g(n) \geq u_1 u_2 \cdots u_v \ell_g(p) \geq \frac{\phi(n)}{y^2 \cdot \prod_{i=1}^v d_i} \geq \frac{x}{y^2 \cdot \log \log n \cdot \prod_{k=1}^v (2k)^{j_k}} \geq \frac{x}{y^3 \cdot \prod_{k=1}^v (2k)^{j_k}}
\]
(recalling that } d_i = (p_i - 1, D) = 2k \text{ if } p_i \in \tilde{S}_k, \text{ and that } n \in \tilde{\Omega}_4(x; j) \text{ implies that } n > x/2. \]

Lemma 11. If } j \in J, \ u \in \tilde{\Omega}_2(x; j), \text{ and } x \geq x_2, \text{ then}
\[
|\{ p : up \in \tilde{\Omega}_4(x; j) \}| > c_2 x/(uy \log x)
\]
where } x_2, c_2 > 0 \text{ are absolute constants.}

Proof. Note that for } j \in J, \ |j| \leq \sum_{k=1}^l E_k/k \ll y/\log y \text{ by (8) and (9). For such vectors } j, \text{ Lemma 3 of [2] implies that the number of primes } p \text{ with max}(x/2u, x^{1/y}) < p \leq x/u, \text{ } (p - 1, D) = 2, \text{ and } (p - 1, p_i - 1) = 2 \text{ for all } p_i \mid u \text{ is } \gg x/(uy \log x). \text{ Thus it suffices to show that}
\[
|\{ p \leq x/u : (p - 1, D) = 2, \ell_g(p) \leq p/y^2 \}| = o(x/(uy \log x)).
\]
As we have seen, for \( j \in J \), \( \|j\| \ll y/\log y \), so that \( u \in \tilde{\Omega}_2(x; j) \) has \( u \leq x^{1/y^2} \) for all large \( x \). Thus, Theorem 6 implies that
\[
\sum_{j \in J} 1 \ll \frac{\pi(x/u)}{y^2} \ll \frac{x}{uy^2 \log x} = o\left(\frac{x}{uy \log x}\right).
\]
The result follows.

**Lemma 12.** If \( j \in J \), then for \( x \geq x_3 \),
\[
\sum_{u \in \tilde{\Omega}_2(x;j)} \frac{1}{u} > \exp\left(-c_3 y \log \log y \right) \prod_{k \leq \log y} \frac{E_k}{j_k!}
\]
where \( x_3, c_3 > 0 \) are absolute constants.

**Proof.** The sum in the lemma is equal to
\[
\frac{1}{j_1!j_2! \cdots j_{\lfloor \log y \rfloor}!} \sum_{(p_1,p_2,\ldots,p_v)} \frac{1}{p_1p_2 \cdots p_v}
\]
where the sum is over sequences of distinct primes where the first \( j_1 \) are in \( \tilde{S}_1 \), the next \( j_2 \) are in \( \tilde{S}_2 \), and so on, and also each \( (p_i - 1, p_j - 1) \mid D \) for \( i \neq j \). Such a sum is estimated from below in Lemma 4 of [2] but without the extra conditions that differentiate \( \tilde{S}_k \) from \( S_k \). The key prime reciprocal sum there is estimated on pages 381–383 to be
\[
E_k \left(1 + O\left(\frac{\log \log y}{\log y}\right)\right).
\]
In our case we have the extra conditions that \( p \nmid g \) and \( (p - 1)/2 | \ell_g(p) \), which alters the sum by a factor of \( 1 + O(\log^5 y/y) \) by Lemma 8. But the factor \( 1 + O(\log^5 y/y) \) is negligible compared with the factor \( 1 + O(\log \log y/\log y) \), so we have exactly the same expression in our current case. The proof is complete.

**3.2. Conclusion.** For brevity, let \( l = \lfloor \log y \rfloor \). We clearly have
\[
T_g(x) \geq \frac{1}{x} \sum_{j \in J} \sum_{n \in \tilde{\Omega}_4(x;j)} \ell_g(n).
\]
By Lemma 10, we thus have
\[
T_g(x) \gg \frac{1}{y^3} \sum_{j \in J} \prod_{k=1}^l (2k)^{-j_k} \sum_{n \in \tilde{\Omega}_4(x;j)} 1.
\]
Now,

\[ \sum_{n \in \tilde{\Omega}_4 (x, j)} 1 = \sum_{u \in \tilde{\Omega}_2 (x, j)} \sum_{v \in \tilde{\Omega}_4 (x, j)} 1, \]

and by Lemma 11, this is

\[ \gg \sum_{u \in \tilde{\Omega}_2 (x, j)} x \frac{1}{uy \log x}, \]

which in turn by Lemma 12 is

\[ \gg \frac{x}{y \log x} \exp \left( \frac{-c_3 y \log \log y}{\log^2 y} \right) \prod_{k=1}^{l} \frac{E_k^{j_k}}{j_k!}. \]

Hence

\[ T_g (x) \gg \frac{x}{y^4 \log x} \exp \left( \frac{-c_3 y \log \log y}{\log^2 y} \right) \sum_{j \in J} \prod_{k=1}^{l} (2k)^{-j_k} \frac{E_k^{j_k}}{j_k!}. \]

Now,

\[ \sum_{j \in \tilde{\Omega}_4 (x, j)} 1 = \sum_{u \in \tilde{\Omega}_2 (x, j)} \sum_{v \in \tilde{\Omega}_4 (x, j)} 1, \]

and by Lemma 11, this is

\[ \gg \sum_{u \in \tilde{\Omega}_2 (x, j)} x \frac{1}{uy \log x}, \]

which in turn by Lemma 12 is

\[ \gg \frac{x}{y \log x} \exp \left( \frac{-c_3 y \log \log y}{\log^2 y} \right) \prod_{k=1}^{l} \frac{E_k^{j_k}}{j_k!}. \]

Hence

\[ T_g (x) \gg \frac{x}{y^4 \log x} \exp \left( \frac{-c_3 y \log \log y}{\log^2 y} \right) \sum_{j \in J} \prod_{k=1}^{l} (2k)^{-j_k} \frac{E_k^{j_k}}{j_k!}. \]

By Lemma 9 we thus have the lower bound in the theorem. The proof is concluded.

4. Averaging over prime moduli — the proofs

4.1. Proof of Theorem 2. Let \( z = (\log x / \log \log x)^{1/2} \), and abbreviate \( \ell_g (p), i_g (p) \) with \( \ell (p), i (p) \), respectively. We have

\[ \sum_{p \leq x} \ell (p) = \sum_{p \leq x, i (p) \leq z} \ell (p) + \sum_{p \leq x, i (p) > z} \ell (p) = A + E, \]
say. Writing $\ell(p) = (p - 1)/i(p)$ and using the identity $1/i(p) = \sum_{u,v|i(p)} \mu(v)/u$, we find that

$$A = \sum_{p \leq x \atop i(p) \leq z} (p - 1) \sum_{uv|i(p)} \frac{\mu(v)}{u}$$

$$= \sum_{p \leq x} (p - 1) \sum_{uv|i(p) \atop uv \leq z} \frac{\mu(v)}{u} - \sum_{p \leq x \atop i(p) > z} (p - 1) \sum_{uv|i(p) \atop uv \leq z} \frac{\mu(v)}{u}$$

$$= A_1 - E_1,$$

say. The main term $A_1$ is

$$A_1 = \sum_{uv \leq z} \frac{\mu(v)}{u} \sum_{p \leq x \atop uv|i(p)} (p - 1).$$

By a simple partial summation using Theorem 5, the inner sum here is

$$\frac{1}{2} x \pi(x) D_g(uv) + O\left(\frac{x^2}{\log^2 x}\right),$$

assuming the GRH. (By replacing $\frac{1}{2} x \pi(x)$ with $\pi(x^2)$ or $\text{li}(x^2)$, the error term here can be strengthened to $O(x^{3/2} \log x)$, but we shall not need this precision.) Thus,

$$A_1 = \frac{1}{2} x \pi(x) \left(\sum_{uv \leq z} \frac{\mu(v)}{uD_g(uv)}\right) + O\left(\frac{x^2}{\log^2 x} \sum_{n \leq z} \left|\sum_{uv=n} \frac{\mu(v)}{u}\right|\right).$$

The inner sum in the $O$-term is $\phi(n)/n$, so the $O$-term is $O(x^2 z/ \log^2 x)$. Recalling that $\text{rad}(n)$ denotes the largest squarefree divisor of $n$, we note that $\sum_{v|k} \mu(v)v = \prod_{p|k} (1 - p) = (-1)^{\omega(k)} \phi(\text{rad}(k))$, and hence

$$\sum_{uv=k} \frac{\mu(v)}{uD_g(uv)} = \sum_{v|k} \frac{\mu(v)v}{D_g(k)k} = \frac{(-1)^{\omega(k)} \phi(\text{rad}(k))}{D_g(k)k}.$$  

On noting that $\phi(\text{rad}(k)) = \phi(k)\text{rad}(k)/k$, we have

$$\sum_{u,v} \frac{\mu(v)}{uD_g(uv)} = \sum_{k \geq 1} \frac{(-1)^{\omega(k)} \text{rad}(k) \phi(k)}{D_g(k)k^2} = c_g.$$  

Thus, with $\psi(h) := h \tau(h)/\phi(h)$,

$$\sum_{uv \leq z} \frac{\mu(v)}{uv D_g(uv)} = c_g - \sum_{k > z} \frac{(-1)^{\omega(k)} \text{rad}(k) \phi(k)}{D_g(k)k^2} = c_g + O(\psi(h)/z),$$
by Proposition 4 and the same argument as in the fourth step of the proof of Theorem 6 (in particular, see (6).) It now follows that

$$ A_1 = x\pi(x) \cdot \left( \frac{c_y}{2} + O(\psi(h)/z) \right) + O(z/\log x). $$

It remains to estimate the two error terms $E, E_1$. Using Theorem 6, we have

$$ E \ll \frac{x}{z} \cdot \frac{\pi(x)}{z} \psi(h) \ll \frac{x\pi(x)\psi(h)}{z^2}. $$

To estimate $E_1$, we consider separately terms with $z < i(p) \leq z^2$ and terms with $i(p) > z^2$, denoting the two sums $E_{1,1}, E_{1,2}$, respectively. Note that

$$ \left| \sum_{ud|n, u\leq z} \mu(v) \right| = \sum_{ud|n, v|d, d \leq z} \frac{\mu(v) v}{d} = \sum_{d|n, d \leq z} (-1)^{\omega(d)} \phi(\text{rad}(d)) \leq \tau(n). $$

We use this estimate for $E_{1,1}$, getting

$$ |E_{1,1}| \leq \sum_{z<n \leq z^2} \tau(n) \sum_{n|i(p), p \leq x} (p-1) \ll x\pi(x) \sum_{z<n \leq z^2} \frac{\tau(n)}{D_g(n)} \ll x\pi(x) \sum_{z<n \leq z^2} \frac{\tau(n)(h,n)}{n\phi(n)}, $$

using Theorem 6 and Proposition 4. An elementary calculation, similar to the one used to deduce (6), then shows that

$$ |E_{1,1}| \ll \frac{x\pi(x)\tau(h)^2 \log z}{z}. $$

For $E_{1,2}$ we use

$$ \left| \sum_{u|n, u\leq z} \mu(v) \right| \leq \sum_{u\leq z} \frac{1}{u} \sum_{v \leq z/u} 1 \leq z \sum_{u \leq z} \frac{1}{u^2} \ll z. $$

Thus, using Theorem 6,

$$ |E_{1,2}| \leq xz \sum_{p \leq x, i(p) > z^2} 1 \ll \frac{x\pi(x)\psi(h)}{z}. $$
Noting that $\psi(h) \ll \tau(h)^2$, we conclude that
\[ \sum_{p \leq x} l(p) = A + E = A_1 - E_{1,1} - E_{1,2} + E \]
\[ = \frac{c_g}{2} x \pi(x) + O \left( \tau(h)^2 \left( \frac{x \pi(x)}{z} + \frac{x \pi(x) z}{\log x} + \frac{x \pi(x) \log z}{z} \right) \right) \]
\[ = \frac{c_g}{2} x \pi(x) + O \left( \frac{x^2 (\log \log x)^{3/2} \tau(h)^2}{(\log x)^{3/2}} \right) \]
\[ = \frac{c_g}{2} x \pi(x) + O \left( \frac{x^2}{(\log x)^{3/2 - 2/\log \log x}} \right), \]
using that $(\log \log x)^{3/2} \tau(h)^2 \ll (\log x)^2/\log \log x$ since $h \ll \log x$. Here we have used Wigert’s theorem for the maximal order of the divisor function. This completes the proof.

4.2. Proof of Proposition 3.

Proof of Proposition 3. We begin with the cases $g > 0$, or $g < 0$ and $e = 0$. Recalling that $D_g(k) = \phi(k)k/\epsilon_g(k)(k,h)$, we find that
\[ c_g = \sum_{k \geq 1} (-1)^{\omega(k)} \frac{\operatorname{rad}(k) \phi(k)}{D_g(k)k^2} = \sum_{k \geq 1} (-1)^{\omega(k)} \frac{\operatorname{rad}(k)(k,h)\epsilon_g(k)}{k^3}. \]
Now, since $\epsilon_g(k)$ equals 1 if $n \mid k$, and 2 otherwise, (12) equals
\[ \sum_{k \geq 1} \frac{(-1)^{\omega(k)} \operatorname{rad}(k)(h,k)}{k^3} + \sum_{n \mid k} \frac{(-1)^{\omega(k)} \operatorname{rad}(k)(h,k)}{k^3} = \sum_{k \geq 1} (f(k) + f(kn)) \]
where the function $f(k) = (-1)^{\omega(k)} \operatorname{rad}(k)(h,k)/k^3$ is multiplicative.

If $p \nmid h$ and $j \geq 1$, we have
\[ f(p^j) = -p/p^{3j}. \]
On the other hand, writing $h = \prod_{p \mid h} p^{e_{p,h}}$ we have
\[ f(p^j) = -p^{1 + \min(j,e_{p,h})}/p^{3j} \]
for $p \nmid h$ and $j \geq 1$. Since $f$ is multiplicative,
\[ \sum_{k \geq 1} (f(k) + f(kn)) = \sum_{k : \operatorname{rad}(k) \mid h} (f(k) + f(kn)) \cdot \sum_{(k,hn)=1} f(k). \]
Now, for $p \nmid h$ and $j \geq 1$, we have $f(p^j) = -\operatorname{rad}(p^j)/p^{3j} = -p/p^{3j}$, hence $\sum_{j \geq 0} f(p^j) = 1 - \frac{p}{p^{1-1/p}} = 1 - \frac{p}{p^{1-1/p}}$ and thus
\[ \sum_{(k,hn)=1} f(k) = \prod_{p \mid hn} F(p) = \prod_{p \mid hn} \left( 1 - \frac{p}{p^3 - 1} \right) = \frac{c}{1 - \frac{p}{p^3 - 1}}. \]
Similarly, \( \sum_{\text{rad}(k)\mid hn} f(k) = \prod_{p\mid hn} F(p) \) and
\[
\sum_{\text{rad}(k)\mid hn} f(kn) = \prod_{p\mid hn} \left( \sum_{j \geq e_n, p} f(p^j) \right) = \prod_{p\mid hn} (F(p) - F(p, e_n, p)).
\]

Hence
\[
\sum_{\text{rad}(k)\mid hn} f(k) + \sum_{\text{rad}(k)\mid hn} f(kn) = \prod_{p\mid hn} F(p) + \prod_{p\mid hn} (F(p) - F(p, e_n, p)) = \prod_{p\mid hn} F(p) \cdot \left( 1 + \prod_{p\mid hn} \left( 1 - \frac{F(p, e_n, p)}{F(p)} \right) \right).
\]

Thus
\[
c_g = \frac{c}{\prod_{p\mid hn} (1 - \frac{p}{p^3 + 1})} \cdot \prod_{p\mid hn} F(p) \cdot \left( 1 + \prod_{p\mid hn} \left( 1 - \frac{F(p, e_n, p)}{F(p)} \right) \right),
\]
which, by (3), simplifies to
\[
c_g = c \cdot \prod_{p\mid h} \frac{F(p)}{1 - \frac{p}{p^3 + 1}} \cdot \left( 1 + \prod_{p\mid hn} \left( 1 - \frac{F(p, e_n, p)}{F(p)} \right) \right).
\]

The case \( g < 0 \) and \( e > 0 \) is similar: using the multiplicativity of \( f \) together with the definition of \( \epsilon_g(k) \), we find that
\[
c_g = \sum_{k \geq 1} (f(k) + f(kn)) - \frac{1}{2} \sum_{j=1}^e \sum_{(k,2)=1} f(2^j k)
= \prod_{p} F(p) + \prod_{p} (F(p) - F(p, e_n, p)) - \frac{1}{2} \cdot (F(2, e + 1) - 1) \cdot \prod_{p \geq 2} F(p)
= \prod_{p} F(p) \left( 1 + \prod_{p\mid hn} \left( 1 - \frac{F(p, e_n, p)}{F(p)} \right) \right) \cdot \left( 1 - \frac{F(2, e + 1) - 1}{2F(2)} \right).
\]

Again using the fact that
\[
\prod_{p\mid h} F(p) = \prod_{p\mid h} (1 - \frac{p}{p^3 + 1}) \prod_{p\mid h} F(p) = c \cdot \prod_{p\mid h} \frac{F(p)}{1 - p/(p^3 + 1)}
\]
the proof is concluded. \( \square \)
5. Acknowledgments

Part of this work was done while the authors visited MSRI, as part of the semester program “Arithmetic Statistics”. We thank MSRI for their support, funded through the NSF. We are very grateful to Michel Balazard for suggesting Arnold’s conjecture to us. In addition we thank Pieter Moree, and the two anonymous referees for helpful comments.
