## Approximate solutions

As we have seen, while the techniques we have developed for finding solutions are powerful, they apply to only a small set of first order equations. So, how do we deal with a general first order equation:

 $y'=f(t,y),\ y(t_0)=y_0$ 

If this initial value problem has a unique solution then we can develop approximative methods to try to find the solution.

# Euler's method

There are a wide variety of numerical methods for solving ODE - a complete discussion is beyond the scope fo this course. We will focus on some of the original methods for X reasons:

- 1. These methods form the basis for more complicated and precise methods
- 2. These methods are, in general, simple and easier to understand
- 3. In this course, we are not concerned with efficiency of finding a solution

Today's material Numerical methods Euler's method

Main ideas:

1. Use the ODE to create a tangent line approximation to the solution curve.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ のの⊙

2. To create a good approximation at each point we iterate this construction.

#### Euler's method Step 1

# Approximate the solution at the point $t = t_0$ by the tangent line:

 $y(t) \approx \underbrace{y_0}_{\text{initial condition}} + \underbrace{f(t_0, y_0)}_{\text{initial slope}} (t - t_0)$ 

The tangent line approximation is accurate for  $t_1$  close to  $t_0$ . So, for  $|t_1 - t_0|$  small enough, we have that  $y(t_1) \approx y_0 + f(t_0, y_0)(t_1 - t_0)$ .

#### Euler's method Step 2

We now repeat Step 1 using the approximate value  $y(t_1) = y_1 = y_0 + f(t_0, y_0)(t_1 - t_0)$ . In other words, create the tangent line approximation:

$$\mathbf{y}(t) \approx \mathbf{y}_1 + f(t_1, \mathbf{y}_1)(t - t_1)$$

Again for  $|t_2 - t_1|$  small enough, we have

 $y(t_2) \approx y_1 + f(t_1, y_1)(t_2 - t_1)$

Today's material Numerical methods Euler's method

#### Euler's method Step k

We now repeat this as many times as we like. If we have completed k - 1 steps and have  $y(t_{k-1}) = y_k$ , we create the tangent line approximation:

$$y(t) \approx y_{k-1} + f(t_{k-1}, y_{k-1})(t - t_{k-1})$$

and for  $|t_k = t_{k-1}|$  small enough, we have

$$y(t_k) \approx y_{k-1} + f(t_{k-1}, y_{k-1})(t_k - t_{k-1})$$

# Euler's method

Results

The result of this method is a list of *t* values  $\{t_0, t_1, \ldots, t_N\}$  and corresponding function values  $\{y_0, \ldots, y_N\}$ . Plotted on a graph, these points give an approximation of the solution curve. Example:  $t_{i+1} - t_i = 0.1, N = 40$

# Euler's method

Error estimates

How close is the approximation to the actual solution? In our example, we can solve explicitly and compare.
