

The Definite Integral

The Area Problem

Upper and Lower Sums

Suppose we want to use rectangles to approximate the area under the graph of $y = x + 1$ on the interval $[0, 1]$.

Upper Riemann Sum

Lower Riemann Sum

$$\frac{31}{20} > 1.5 > \frac{29}{20}$$

As you take more and more smaller and smaller rectangles, if f is nice, both of these will approach the real area.

n	U	L
100	1.505000000	1.495000000
150	1.503333333	1.496666667
200	1.502500000	1.497500000
300	1.501666667	1.498333333
500	1.501000000	1.499000000

In general: finding the Area Under a Curve

Let $y = f(x)$ be given and defined on an interval $[a, b]$.

Break the interval into n equal pieces.

Label the endpoints of those pieces x_0, x_1, \dots, x_n .

Let $\Delta x = x_i - x_{i-1} = \frac{b-a}{n}$ be the width of each interval.

The **Upper Riemann Sum** is: let M_i be the *maximum* value of the function on that i^{th} interval, so

$$U(f, P) = M_1\Delta x + M_2\Delta x + \cdots + M_n\Delta x.$$

The **Lower Riemann Sum** is: let m_i be the *minimum* value of the function on that i^{th} interval, so

$$L(f, P) = m_1\Delta x + m_2\Delta x + \cdots + m_n\Delta x.$$

Take the limit as $n \rightarrow \infty$ or $\Delta x \rightarrow 0$.

Sigma Notation

If m and n are integers with $m \leq n$, and if f is a function defined on the integers from m to n , then the symbol $\sum_{i=m}^n f(i)$, called

sigma notation, is means

$$\sum_{i=m}^n f(i) = f(m) + f(m+1) + f(m+2) + \cdots + f(n)$$

Examples: $\sum_{i=1}^n i = 1 + 2 + 3 + \cdots + n$

$$\sum_{i=1}^n i^2 = 1^2 + 2^2 + 3^2 + \cdots + n^2$$

$$\sum_{i=1}^n \sin(i) = \sin(1) + \sin(2) + \sin(3) + \cdots + \sin(n)$$

$$\sum_{i=0}^{n-1} x^i = 1 + x + x^2 + x^3 + x^4 + \cdots + x^{n-1}$$

The Area Problem Revisited

$$\text{Upper Riemann Sum} = \sum_{i=1}^n M_i \Delta x$$

$$\text{Lower Riemann Sum} = \sum_{i=1}^n m_i \Delta x,$$

where M_i and m_i are, respectively, the maximum and minimum values of f on the i th subinterval $[x_{i-1}, x_i]$, $1 \leq i \leq n$.

$$n = 5$$

Example

Use an Upper Riemann Sum and a Lower Riemann Sum, first with 8, then with 100 subintervals of equal length to approximate the area under the graph of $y = f(x) = x^2$ on the interval $[0, 1]$.

The Definite Integral

We say that f is integrable on $[a, b]$ if there exists a number A such that

$$\text{Lower Riemann Sum} \leq A \leq \text{Upper Riemann Sum}$$

for all n . We write the number as

$$A = \int_a^b f(x) dx$$

and call it the **definite integral** of f over $[a, b]$.

Trickiness: Who wants to find maxima/minima over every interval? Especially as $n \rightarrow \infty$? Calculus nightmare!!

More Riemann Sums

Let f be defined on $[a, b]$, and pick a positive integer n .

Let

$$\Delta x = \frac{b - a}{n}$$

Notice:

$$x + 0 = a, \quad x_1 = a + \Delta x, \quad x_2 = a + 2\Delta x, \quad x_3 = a + 3\Delta x, \dots$$

So let

$$x_i = a + i * \Delta x.$$

More Riemann Sums

Let f be defined on $[a, b]$, and pick a positive integer n .

Let

$$\Delta x = \frac{b - a}{n} \quad \text{and} \quad x_i = a + i * \Delta x.$$

Then the Right Riemann Sum is

$$\sum_{i=1}^n f(x_i) \Delta x,$$

and the Left Riemann Sum is

$$\sum_{i=0}^{n-1} f(x_i) \Delta x_i.$$

Integrals made easier

Theorem

If f is "Riemann integrable" on $[a, b]$, then

$$\int_a^b f(x) dx = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(c_i) \Delta x_i$$

where c_i is **any** point in the interval $[x_{i-1}, x_i]$.

Punchline: We can calculate integrals by just using right or left sums! (instead of upper or lower sums)

Example: Set up left and right limit definitions of $\int_1^4 e^x dx$.
Remember that

n is the number of pieces we've divided the interval into, and
 i indexes the terms in the sum (labels the rectangles).

Each piece:

$$\Delta x = \frac{4-1}{n} = \frac{3}{n} \quad x_i = 1 + i * \Delta x = 1 + \frac{3i}{n}$$

So, the **left Riemann sum** is

$$\sum_{i=0}^{n-1} f(x_i) \Delta x = \sum_{i=0}^{n-1} e^{1+\frac{3i}{n}} \left(\frac{3}{n}\right) = \frac{3e}{n} \sum_{i=0}^{n-1} \left(e^{3/n}\right)^i$$

and the **right Riemann sum** is

$$\sum_{i=1}^n f(x_i) \Delta x = \sum_{i=1}^n e^{1+\frac{3i}{n}} \left(\frac{3}{n}\right) = \frac{3e}{n} \sum_{i=1}^n \left(e^{3/n}\right)^i$$

So

$$\int_1^4 e^x dx = \lim_{n \rightarrow \infty} \frac{3e}{n} \sum_{i=0}^{n-1} \left(e^{3/n}\right)^i = \lim_{n \rightarrow \infty} \frac{3e}{n} \sum_{i=1}^n \left(e^{3/n}\right)^i.$$

On your own:

1. Set up the left limit definition of $\int_{-1}^5 \sin(x) dx$.
2. Rewrite the following expressions as $\int_a^b f(x) dx$ by identifying $f(x)$, a , and b . Also, identify if I've used the left or right Riemann sums.

(a) $\lim_{n \rightarrow \infty} \sum_{i=0}^{n-1} \left(\left(6 + \frac{7i}{n} \right)^3 + 2 \right) \left(\frac{7}{n} \right)$

(b) $\lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{2 + \frac{i}{n}}{2 - \frac{i}{n}} \left(\frac{1}{n} \right)$

Properties of the Definite Integral

- $\int_a^a f(x)dx = 0.$
- If f is integrable and
 - $f(x) \geq 0$ on $[a, b]$, then $\int_a^b f(x)dx$ equals the area of the region under the graph of f and above the interval $[a, b]$;
 - $f(x) \leq 0$ on $[a, b]$, then $\int_a^b f(x)dx$ equals the **negative** of the area of the region between the interval $[a, b]$ and the graph of f .
- $\int_b^a f(x)dx = -\int_a^b f(x)dx.$

4. If $a < b < c$, $\int_a^b f(x)dx + \int_b^c f(x)dx = \int_a^c f(x)dx$

5. If f is an **even** function, then

$$\int_{-a}^a f(x) dx = 2 \int_0^a f(x) dx.$$

Area I = Area II

6. If f is an **odd** function, then

$$\int_{-a}^a f(x) dx = 0.$$

Area I = Area II

Example

$$\text{If } f(x) = \begin{cases} x, & x < 0, \\ \sqrt{1 - (x - 1)^2}, & 0 \leq x \leq 2, \\ x - 2, & x \geq 2, \end{cases} \text{ what is } \int_{-1}^3 f(x) dx?$$

Mean Value Theorem for Definite Integrals

Theorem

Let f be continuous on the interval $[a, b]$. Then there exists c in $[a, b]$ such that

$$\int_a^b f(x) dx = (b - a)f(c).$$

Definition

The *average value* of a continuous function on the interval $[a, b]$ is

$$\frac{1}{b - a} \int_a^b f(x) dx.$$
