Math 5: Music and Sound FALL 2008: Final

This was quite a band exam:

A/B boundary 68/80

8/0

55/80

-1

D "

3 hours, 9 questions, 80 points total

Try to show working. Heed the points available for each question. Try the bonuses once the rest is ok. The last page has useful information. Good luck, have fun, and it was great to have you in the course!

## 1. [9 points]

2

3

2

2

(a) What is the frequency of the pitch C8 (the highest note on the piano) in the equal-tempered system?

C5 is 3 semitores above A4 (440 Hz)
$$f_{C5} = 2^{3/12} \cdot 440 \qquad \text{then go up 3 octaves}$$

$$f_{C8} = 2^3 \cdot 2^{3/2} \cdot 440 = 4186 \text{ Hz}$$

(b) The second column of the touchtone keypad is encoded by frequency 1336 Hz. What musical pitch is this nearest, and what is the error from this pitch in *cents*?

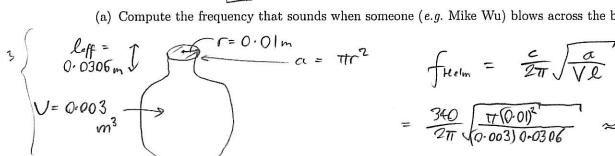

ratio to 
$$R = \frac{1336}{440}$$
  $n = 12 \frac{\ln R}{\ln 2} = 19.23$   
 $\propto 1 \text{ certare } + 7 \text{ semi3}.$   
So nearest E6, 23 cents sharp.  
(error above).

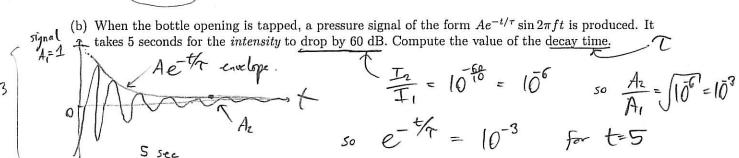

(c) Construct the frequency ratio between C and the D above it in the Pythagorean tuned C major (diatonic) scale. (Briefly show working)

(d) If you continued using this Pythagorean construction to compute *all* notes of the chromatic scale, what error in cents would occur when you eventually returned to (and compared against) your starting note?

$$(\frac{3}{2})^{12} = 129.75$$
, is close to 7 octaves =  $2^7 = 128$   
cent error =  $1200 \frac{\ln \frac{129.75}{128}}{\ln 2}$   $1 = 23.5$  too sharp when reach C again.

- 2. [10 points] An empty 3 liter soda bottle has a neck with radius 1 cm and effective length 3.06 cm.
  - (a) Compute the frequency that sounds when someone (e.g. Mike Wu) blows across the bottle.

so 
$$\frac{A_2}{A_1} = \sqrt{|\vec{0}|^6} = |\vec{0}|^6$$

$$50 - \frac{5}{7} = \log(10^{-3})$$

$$50 - \frac{5}{7} = \log(10^{-3})$$
  $\Rightarrow 7 = \frac{-5}{\log(10^{-3})} = 0.712s$ 

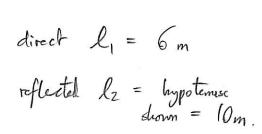

(c) Someone now excites the bottle by sounding a pure tone. What range of frequencies would cause at least half the maximum response amplitude inside the bottle? (If you didn't get parts a and/or b, give your answer in symbols.) Sketch a response curve to illustrate this, labeling your axes.

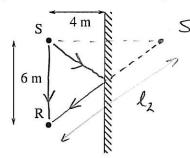

Q factor = 
$$\pi f_{Helin}$$
 =  $\pi (100) \cdot 0.72 \approx 227$   
 $\Delta f = f_{Q} \approx 0.44 \text{ Hz}$ , so range is  $f_{Helin} \stackrel{L}{2}$   
=  $[99.78, 100.22] \text{ Hz}$ 

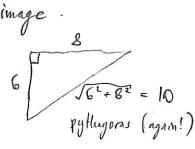

> f driving freq. (d) How much water should be poured into the bottle to change the pitch by one octave? (does it go up or down?)

So, 3 must be displaced by water, re 2.25 lites of water.

4

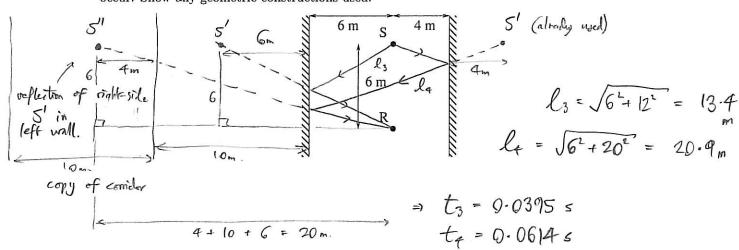

(b) What is the lowest pure tone frequency emitted that would cause destructive interference of these two paths, for this listener?

2 signals

regnises where 
$$T = period$$
. (qually  $(n+\frac{1}{2})T$ )

(queally (n+ 1/2)T)

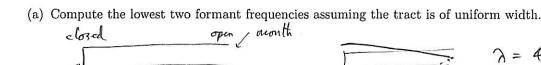

So 
$$T = 2(t_2 - t_1) = 0.0235$$
,  $f = \frac{1}{2} = 42.5 \text{ Hz}$ . (c) A second parallel wall is added 10 m to the left as shown below. Find two *new* travel times which occur. Show any geometric constructions used.

(d) [BONUS] If the speaker emits a loud but short click, what would you expect the tail (decaying part) of the echo the listener hears to be like, and why? (diagrams help)

There is an infinite array of images 5", 5", etc. which contribute to the tail of the echo: In the limit the hypotenuse of totale approaches the horizontal distance, so these path lengths approach the set {20n-8, 20n, 20n+8}

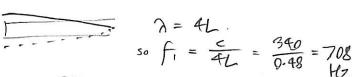

So the signal is a flutter-echo of the form; It approaches a period of 20 = 0.05885.

4. [10 points] A child's vocal tract behaves like a closed-open pipe 12 cm long.

$$f_{2} = \frac{3c}{4L} = \frac{708}{0.48} = \frac{708}{Hz}$$

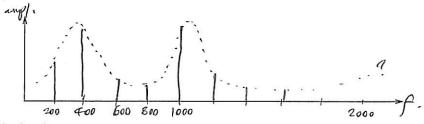

(b) Sketch graphs of a spectrum you might hear with this tract shape if the child were...

(be sure to label your axes and give some values on the horizontal axis)

(c) The child now breathes harmless but dense sulphur hexaflouride which halves the speed of sound in their tract. Redo the new spectrum for the first case above...

formants are  $\frac{C}{4L}$ ,  $\frac{3C}{4L}$ 50 they are halved if C is.  $\Rightarrow$   $f_1 = 354$ ,  $f_2 = 1063$ . singing with pitch 200 Hz:

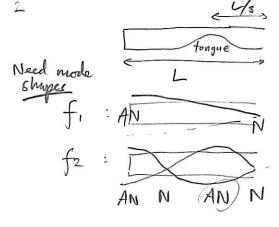

Explain what has changed and what has not:

The set of partials at 200 n, n=1,2,...

the formants F1 LF2.

(d) Returning to normal air, the child presses their tongue upwards to constrict the tract 1/3 of the way down from the mouth. What happens to their first two formants? (relative to part a)

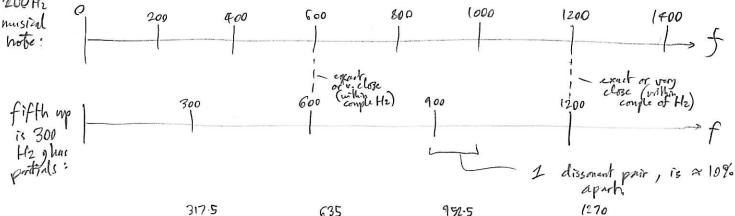

(e) Relative to a uniform vocal tract, how could the child easily shape their tract to lower both F1 (ie part a)

Need to constrict at a N for both modes, which occurs at the =) close the month somewhat.

(Also correct: open the truck near rocal folds, sounds harder to me!)

## 5. [7 points]

(a) A musical note with pitch 200 Hz is accomanied by another, either a perfect fifth above it, or a minor sixth above it. Compare the resulting dissonance for these two situations using Helmholtz's partials of theory (consider only below 1400 Hz)

952.5 r 640 ·r 960 er 1280 minor sixth 317-5 Hz (equal-temperal)

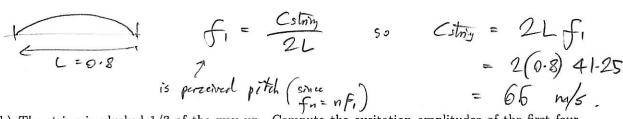

or \$ 200 = 320 Hz (just intenstra). dissonant 213 sonances 3

(b) What is the probable perceived pitch of a sound with partials at 432, 601, 900, 1199, 1435 Hz. ratios 1-391 1-498 1-332 1=197 = 3/2 = 4/3 1435 = 3.32 no special rates

where F = 300 Hz is perceived pitch. 601 = 2f  $900 \approx 3f$   $1199 \approx 4f$ 

(c) [BONUS] How it can be that the piano sounds better when its octaves are tuned with ratio slightly (Huy are increasingly above nf Fof n=1,2,-- When n is large). Consonance requires ording up of partial so this happens when octors is terred eg. 2.03:1

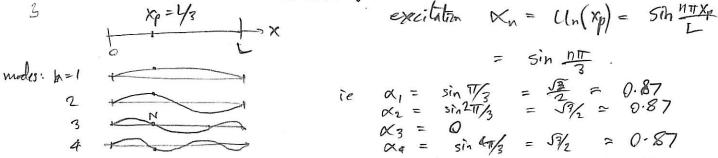

- 6. [9 points] Here you model the sound of the lowest string of the electric bass, which has length 0.8 m.
  - (a) The string produces a note of E1 (41.25 Hz). What is the speed of transverse waves on this string?

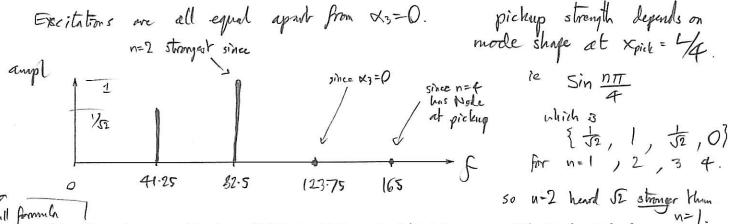

(b) The string is plucked 1/3 of the way up. Compute the excitation amplitudes of the first four modes of the string (are any zero?)

yes, \$\prec{1}{3} = 0\$

Since has a node where pluck.

(c) The amplified signal is from an electric pickup placed 1/4 of the way up. Use this and part b) to compute (relative) amplitudes of the first four modes heard, and sketch the resulting spectrum.

the full formula (d) A finger is now used to damp (lightly touch) the string 2/5 of the way up. What is the pitch of the sound produced? (note this is true regardless of where it is now plucked)

5

(0

1

The n=5 mode is the first one with a N (rode) at xd = \frac{2}{5}L.

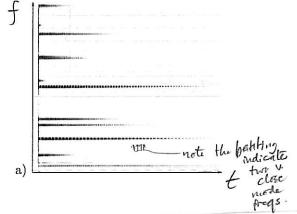

Cr, or where elective pirchayo

You can check flust u=10, 15, etc Hir

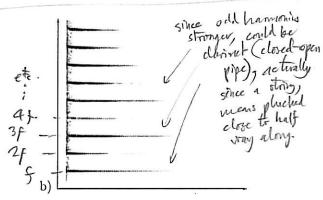

=> spectrum contains only partial at multiples of 5f, × 206.25 Hz

6 So this is the pitch heard

7. [7 points] The following show actual spectrograms, with frequency (0 to 4000 Hz) vertical, and time (0 to 3 sec) horizontal. Describe pitch (has one?), decay, timbre, and use to state an instrument and method which could have produced it: (if stuck think about the spectra)

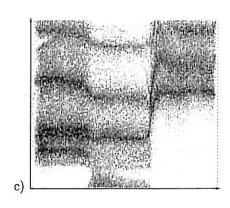

sound state suddenly with seemingly unrelated partials, each decaying at different rates. Suggests struck metal object, eg bell, (probably no definite pitch), or drum. Timbre start harsh then quickly

Also struck since partial decay, again with different cleany times.

However all A fregs appear to be multiples of some fundamental f, strong sense of pitch.

An object with these mode fregs is either a strong, or pipe (it was plucked string) Timbre again becomes mellower over time, start harsher than a).

Spectrum doesn't contain partials (spikes) so it is not a freely-vibrating object. The peaks are wide & seem to shift in Time suggesting a resonator (with 3-4 mades) changing shape, driven by white noise.

It is 3 whispered vowel sounds (showing formults) No definite pitch.

Which of the above, if any, will be periodic signals (at least while they last), and why?

b is the only one whos partials are all multiples of some fundamental, as is required for a periodic

- 8. [9 points] Short unrelated calculation problems.
  - (a) What is the period of the signal  $\sin(100\pi t + \pi/4)$ ? (as usual, t is time in seconds)

$$W + S_0 W = 100\pi$$

$$period T = \frac{2\pi}{W} = \frac{2\pi}{100\pi} = \frac{1}{50} S$$
or 0.025.

(b) You are a stationary listener. How fast does a source of sound need to travel towards you so that its pitch appears to change by an octave?

proving source Doppler formula: Since coming township, pitch goes up by octave fobs = 
$$\frac{1}{1-1/2}$$
 f but were told fobs =  $\frac{1}{1-1/2}$  since octave up.

$$\frac{1}{1-1/2} = \frac{1}{1-1/2} =$$

(c) Compute the intensity in dB of an orchestra radiating 5 W acoustic power in all directions, at a distance of  $100~\mathrm{m}$ .

$$P=5W$$

$$T = \frac{1}{4\pi r^{2}} \text{ from area of sphere radius } r.$$

$$= \frac{5}{4\pi (100)^{2}} = 3.48 \times 10^{-5} \text{ W/m}^{2}$$

$$C=100$$

$$AB = 10 \log_{10} \frac{T}{10^{-12}} = 76.0 \text{ AB}.$$

(d) A small animal hears a pure tone of 680 Hz. The phase difference between the signal at its left and right ears is then  $\pi/5$  radians. From this find the smallest possible distance between its ears. (Ignore delays due to curvature of the head, *i.e.* assume straight-line travel of sound)

pure tone head. Let's assume the sound arrives along the line from L to hear.

Then planse differents 
$$\phi = \frac{L \cup X}{C}$$
 where  $\chi = \frac{1}{2}$  inter-ear distance.

So  $\chi = \frac{C}{C} = \frac{340.7}{2\pi.680} = 0.05$  m or  $5$  Cm.

Notice that if the incident sound comes from another direction, the ears could only

more thron this distance agast. (recall morksheet on direction sensitivity).

9. [9 points] Explanation questions: points for correct and precise use of concepts. Diagrams can help.
(a) Explain the difference between frequency and pitch.
frequency: repetitions per second of some periodic signal, or some partial
pitch: a perceived (ic psychoacoustie) frequency often due to one or many pointials being included together by the ear-brain system.  (b) Explain what a Fourier series is and what kind of signals it can and cannot represent.  Choose a fundamental Arguency of.
A Fernier series is a sum of pure tones at fright f, 25, 36, etc.
It can represent only signals periodic with period T = f (or, strictly, also Tri, n=1, In tems of signal graphs over one period: It can't represent non-periodic signals.
$g(t) = f^{9} + \cdots = \alpha_{1} \sin(2\pi t + \beta_{1}) + \alpha_{2} \sin(4\pi t + \beta_{2})$
(c) Explain how a Tuvan throat singer produces a high-pitched 'whistle-like' melody by singing.
The voice is a source with spectrum 111111115 which gets multiplied
by the spectrum of the filter with is the vocal track resonator.
The Turan changes the vocal Fract cavity to create a formant with a very
high Q factor (eg. 20 or more), giving spectrum fillings
This amplifies a single partial of the source, giving heard pitch. V. narrow formant
(d) Explain why the musical interval between a closed-open and open-open pipe of the same length is not exactly an octave (is it bigger or smaller?)
e= end corr. = 0.6 × radius. closed-open has one end-correction  c-o:  Leff= L+e Open-open has two " s
o-0: $\frac{e}{L_{eff} = L + 2e}$ $\int_{c_0}^{e} \frac{e}{A(L + e)} \int_{c_0}^{e} A_{L_0}^{\dagger} = 2 \frac{L_0}{L_0} + 2e$ $\int_{c_0}^{e} \frac{e}{A(L + e)} \int_{c_0}^{e} A_{L_0}^{\dagger} = 2 \frac{L_0}{L_0} + 2e$ $\int_{c_0}^{e} \frac{e}{A(L + e)} \int_{c_0}^{e} A_{L_0}^{\dagger} = 2 \frac{L_0}{L_0} + 2e$ $\int_{c_0}^{e} \frac{e}{A(L + e)} \int_{c_0}^{e} A_{L_0}^{\dagger} = 2 \frac{L_0}{L_0} + 2e$ $\int_{c_0}^{e} \frac{e}{A(L + e)} \int_{c_0}^{e} A_{L_0}^{\dagger} = 2 \frac{L_0}{L_0} + 2e$ $\int_{c_0}^{e} \frac{e}{A(L + e)} \int_{c_0}^{e} A_{L_0}^{\dagger} = 2 \frac{L_0}{L_0} + 2e$ $\int_{c_0}^{e} \frac{e}{A(L + e)} \int_{c_0}^{e} A_{L_0}^{\dagger} = 2 \frac{L_0}{L_0} + 2e$
(e) [BONUS] In class we learned about two ways in which digital (as opposed to analog) sound recording may change (distort) a signal in order to convert it to data. Describe one of these, and the type of distortion produced.
Either i) sampling in time may fold back frequencies above frameling down to lower freqs. (see worksheef on this).
or ii) quantization of signal amplitude from to III } finite number
